INTRODUCTION: The formulae developed in (Part II a) of this report are applied to the following situation. A ballistic missile carrying a thermo-nuclear warhead is fired against a point target, i.e. perhaps a launching site of an enemy ballistic missile. The terminal ballistic characteristics of our missile suggests that with a perfect altimeter the distribution of burst points about the arming point is an uncorrelated bivariate normal distribution in range and deflection. If σ_r and σ_d denote the standard deviations of burst points about the mean in range and deflection respectively and σ_A the standard deviation about the mean value zero of an assumed normal distribution of fuze function errors for an altimeter type fuze, then the parameters needed to effect the calculations are obtained by means of the formulae:

$$\sigma_x^2 = \sigma_r^2 + \sigma_A^2 \cot^2 \theta$$

$$\sigma_v^2 = \sigma_d^2$$

$$\sigma_z^2 = \sigma_A^2$$

$$\rho_{xz} = \frac{\rho_{xz}}{\sigma_x \sigma_z} = \frac{\sigma_A^2 (\cot \theta)}{\sigma_x \sigma_z} = \frac{\sigma_A \cot \theta}{\sqrt{\sigma_r^2 + \sigma_A^2 \cot^2 \theta}}$$

D. O. F. L.

DOCUMENT CONTROL

RESTRICTED DATA

Regrading data cannot be predetermined

This document contains restricted data as defined in the Atomic Energy Act of 1946. Its transmittal or the disclosure of its contents in any manner to an unauthorized person is prohibited.

SECRET

SECRET

The mean burst height \bar{z} was chosen so that the probability that the fireball touches the ground does not exceed 5%; i.e.

$$\bar{z} = b + k \sigma_z$$

where b , the fireball radius was calculated from the formula

$$b = 180 \sqrt[3]{Y},$$

Y is the yield in kilo-tons and $k = 1.65$ assures the 5% level.

In this particular application, the mean range was left as a parameter, because we wished to discover if overshooting or undershooting the target (in range) would increase the probability of damage. Thus, $\bar{x} = 0$ corresponds to shooting so that the mean burst point is directly over the target, $\bar{x} > 0$ corresponds to overshooting by the amount \bar{x} and $\bar{x} < 0$ to undershooting by the amount \bar{x} .

Input Data: the following values of the parameters were used as input data:

$Y = 1$ megaton, which implies $b = 1800$ feet

$\sigma_r = 6,000, 12,000$ feet

$\sigma_d = 1/3 \sigma_r$

$\sigma_A = 0, 500, 1000, 1500$ feet

$\Theta = 340^\circ, 330^\circ, 320^\circ$

$\bar{x} = -2000, -1000, 0, +1000, +2000$ feet.

$s = 1000, 5000, 6000$ feet

Output Data: The results of the calculations are given in the following table: graphs are included to illustrate the effect of certain parameters.
